

Running Jupyter Notebook with Docker

A short guide to running Jupyter on your own machine and keeping your work saved to your local disk.

1. Pull the image

```
docker pull quay.io/jupyter/scipy-notebook:latest
```

This image includes Python and common scientific libraries (NumPy, pandas, scikit-learn, matplotlib).

2. Create a folder for your work

Make a folder on your disk, for example `jupyter-work`. All your notebooks will be saved here.

3. Run the container

Windows (PowerShell or CMD):

```
docker run -it --rm -p 8888:8888 -v C:\Users\YOURNAME\jupyter-work:/home/jovyan/work quay.io/jupyter/scipy-notebook:latest
```

Mac or Linux:

```
docker run -it --rm -p 8888:8888 -v ~/jupyter-work:/home/jovyan/work quay.io/jupyter/scipy-notebook:latest
```

Replace `YOURNAME` with your username. The path before the colon is the folder on your disk. Leave the path after the colon as it is.

4. Open it in your browser

The terminal prints a line with a token, something like:

```
http://127.0.0.1:8888/lab?token=abc123...
```

Copy the full URL into your browser. The token is required. Without it, Jupyter will not let you in.

5. Save only inside the work folder

Work and save only inside the **work** folder. Everything in that folder lands on your disk and stays there after you shut the container down. Anything saved elsewhere is lost.

Quick check that it works: Create a test file inside the work folder. Look in `jupyter-work` on your disk. If it is there, the connection is correct.

Troubleshooting

- **Port 8888 already in use** — change the left number, for example `-p 8889:8888`, then open `localhost:8889`
- **Windows denies access to the folder** — open Docker Desktop, go to Settings, Resources, File Sharing, and add your folder
- **Uploaded a file with drag-and-drop** — if you drag a notebook into Jupyter in the browser instead of placing it in the work folder on disk, the file stays inside the container and is lost when it shuts down
